Let's talk about text

Section 4: Styling Typography

Font Size

Generally it's best practice to use rems for most typography.

```
h2 { font-size: 1.5rem; }
h3 { font-size: 30px; }
```

Font Family

There are only a limited number of 'Web Safe' fonts including Arial, Helvetica, Times New Roman, Times, Courier New.

```
h1 { font-family: 'Arial'; }
h2 { font-family: 'Helvetica'; }
p { font-family: 'Times New Roman'; }
```

This font is Arial

This font is Impact

This font is Helvetica

This font is Times New Roman

This font is Courier New

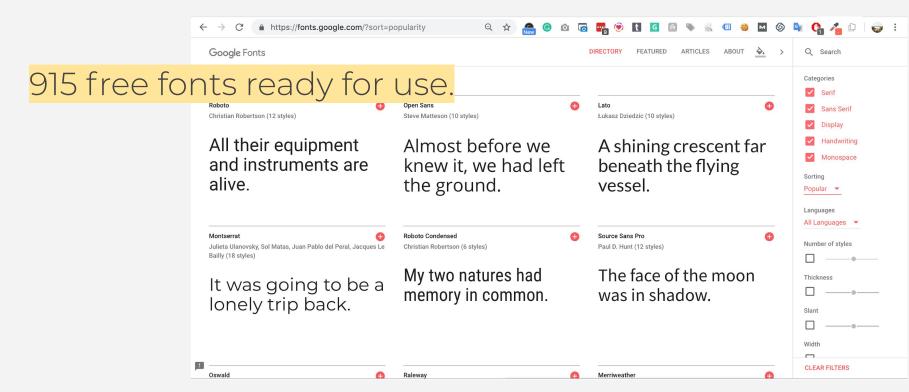

This font is Comic Sans

This font is Verdana

This font is Georgia

Only problem is all of these are all pretty generic.

Say hello to Google Fonts

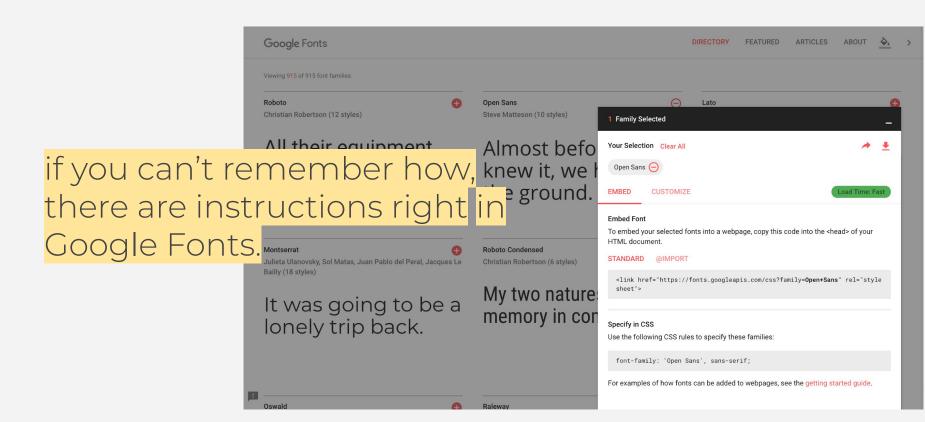

Google Fonts

First add the link to the <head> of your html.
In Codepen you access this via Settings > HTML > Stuff for <head>

```
<link href="https://fonts.googleapis.com/css?family=Roboto"
rel="stylesheet">
```

Then in the css, specify which elements you want to use which fonts.

```
h1 { font-family: "Roboto"; }
```

Font Weight

This determines the thickness or weight of a font.

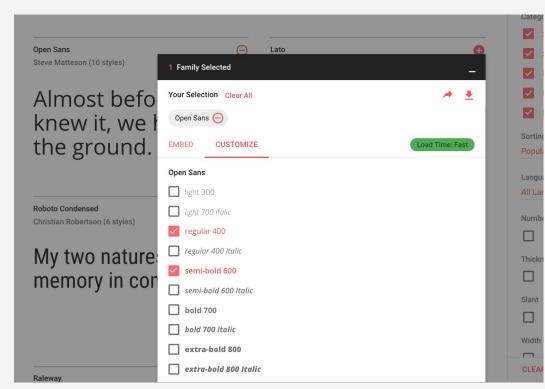

```
h1 { font-weight: normal; }
h2 { font-weight: bold; }
p { font-weight: 400; }
```

Check which font-weights are available

Each font-family has different options for the font-weight.

Make sure you check which font-weights are available and select in *Google Fonts* > Customize which ones you want to be able to use.

Here, we're making only 400 and 600 available.

Text Align

The alignment can be left, right, center or justify.

```
body { text-align: center; }
h2 { text-align: right; }
p { text-align: justify; }
```

Underlines (text-decoration)

Controlling the default underline on links

```
a { text-decoration: underline; }
Click Me
```

a { text-decoration: none; }

Text-Transform

This allows you to transform the capitalisation of the text.

h1 { text-transform: none; }

Hello World

h1 { text-transform: uppercase;}

HELLO WORLD

Letter spacing

This determines the space between each letter, the default is 'normal'

h1 { letter-spacing: normal; }

HELLO WORLD

h1 { letter-spacing: 4px; }

HELLO WORLD

Line Height

This determines the height of each line of text.

```
p { line-height: 1; }
```

This is a short paragraph, that spreads over two lines.

```
p { line-height: 1.5; }
```

This is a short paragraph, that spreads over two lines.

Space between paragraphs

If you want to create space not between every line of text but between each separate paragraph you use margin bottom.

```
p { margin-bottom: 0; }
```

p { margin-bottom: 1rem; }

This is a short paragraph, that spreads over two lines. This is a second paragraph.

This is a short paragraph, that spreads over two lines.

This is a second paragraph.

Default styles

Targeting the **body** targets all elements on the page.

Targeting **multiple selectors** at once (separated with a comma) allows us to style all the headings at the same time and keep our CSS more efficient.

```
body {
  font-family: "Lato";
  color: rgb(60,60,65);
}
```

```
h1, h2, h3 {
  font-weight: 600;
  color: orange;
  letter-spacing: 2px;
  text-transform: uppercase;
}
```
